

The background features a complex, abstract design. It includes a network of red lines connecting green dots, resembling a graph or data structure. There are also vertical lines of varying thicknesses and a grid of small plus signs. A large, light-colored geometric shape, possibly a stylized letter 'A' or a triangle, is overlaid on the right side. The overall color palette is muted, with shades of red, green, and brown.

Frequent Pattern Mining in Data Streams

Challenges for Data Analysis in Data Streams

❑ Data Streams

- ❑ Features: Continuous, ordered, changing, fast, huge volume
- ❑ Contrast with traditional DBMS (finite, persistent data sets)

❑ Characteristics

- ❑ Huge volumes of continuous data, possibly infinite
- ❑ Fast changing and requires fast, real-time response
- ❑ Data stream captures nicely our data processing needs of today
- ❑ Random access is expensive: **single scan algorithm** (*can only have one look*)
- ❑ Store only the summary of the data seen thus far
- ❑ Most stream data are at low-level and multi-dimensional in nature, needs multi-level and multi-dimensional processing

Architecture: Stream Data Processing

SDMS (Stream Data Management System)

User/Application

Continuous Query

Results

Multiple streams

Q: How to mine frequent patterns in data streams?

Stream Query Processor

Scratch Space
(Main memory and/or Disk)

Stream Data Mining Tasks

- ❑ Stream mining vs. stream querying
 - ❑ Stream mining shares many difficulties with stream querying
 - ❑ E.g., single-scan, fast response, dynamic, ...
 - ❑ But often requires less “precision”, e.g., no join, grouping, sorting
 - ❑ Patterns are hidden and more general than querying
- ❑ Stream data mining tasks
 - ❑ Pattern mining in data streams 
 - ❑ Multi-dimensional on-line analysis of streams
 - ❑ Clustering data streams
 - ❑ Classification of stream data
 - ❑ Mining outliers and anomalies in stream data

Mining Approximate Frequent Patterns

- ❑ Mining **precise** frequent patterns in stream data: **Unrealistic**
 - ❑ Cannot even store them in a compressed form (e.g., FPtree)
- ❑ **Approximate answers** are often sufficient for pattern analysis
 - ❑ Ex.: A router
 - ❑ is interested in all flows whose **frequency** is at least **1% (σ)** of the entire traffic stream seen so far
 - ❑ and feels that **1/10 of σ ($\epsilon = 0.1\%$) error** is comfortable
- ❑ How to mine frequent patterns with **good approximation**?
 - ❑ Lossy Counting Algorithm (Manku & Motwani, VLDB'02)
 - ❑ Major ideas: Not to keep the items with very low support count
 - ❑ Advantage: Guaranteed error bound
 - ❑ Disadvantage: Keeping a large set of traces

Lossy Counting for Frequent Single Items

Divide stream into 'buckets' (bucket size is $1/\epsilon = 1000$)

First Bucket of the Stream

Empty (summary)

At bucket boundary, decrease all counters by 1

Next Bucket of the Stream

Approximation Guarantee

- Given: (1) support threshold: σ , (2) error threshold: ϵ , and (3) stream length N
- Output: items with frequency counts exceeding $(\sigma - \epsilon) N$
- How much do we undercount?

If stream length seen so far = N and bucket-size = $1/\epsilon$

then **frequency count error** \leq # of buckets

$$= N/\text{bucket-size} = N/(1/\epsilon) = \epsilon N$$

- Approximation guarantee
 - No false negatives
 - False positives have true frequency count at least $(\sigma - \epsilon)N$
 - Frequency count underestimated by at most ϵN

Other Issues and Recommended Readings

- ❑ Other issues on pattern discovery in data streams
 - ❑ Space-saving computation of frequent and top-k elements (Metwally, Agrawal, and El Abbadi, ICDT'05)
 - ❑ Mining approximate frequent k-itemsets in data streams
 - ❑ Mining sequential patterns in data streams
- ❑ Recommended Readings
 - ❑ G. Manku and R. Motwani, “Approximate Frequency Counts over Data Streams”, VLDB'02
 - ❑ A. Metwally, D. Agrawal, and A. El Abbadi, “Efficient Computation of Frequent and Top-k Elements in Data Streams”, ICDT'05
